

DASHConfig

A DASHConfig instance is used to configure the DASH instance for use.

- **USER EMAIL**
 - An identifier used to uniquely identify a user in the DASH system. Must be an email address.
- **TEAM IDENTIFIER**
 - The unique identifier for the team provided by DASH. This is used to tailor the experience per team.
- **PUSH DEVICE TOKEN**
 - The push device token for the current app. This is used to send DASH outbid notifications on the team's behalf.
- **DEVICE TYPE**
 - Android or iOS
- **DISTRIBUTOR IDENTIFIER**
 - A unique identifier for the app distributor implementing DASH in their app. We will provide this to you.
- **APPLICATION IDENTIFIER**
 - A unique identifier for the individual application using DASH. (The bundle identifier for iOS apps)

DASH

A DASH instance can be used as an app wide singleton (by using team) or as a local instance (by using the initializer). It is the main class for interacting with the SDK. Use this instance to handle deep link URLs and to instantiate a view controller to show the DASH interface.

- **func start(with config: DASHConfig)**
 - Initializes the SDK. Call this once before any other methods.
- **func canHandleDASHLink(with url: URL) -> Bool**
 - Returns true if the url passed in should be handled by DASH. Ex: URLs from DASH notifications will return true.
- **func handleDASHLink(with url: URL, completion: @escaping DASHCompletion)**
 - Tells DASH to handle the link. Completion is called once navigation has finished and is ready for display. Ex: DASH will navigate to the correct auction item when passed the URL from an outbid notification.
- **func dashViewController() -> UIViewController**
 - Returns a DASH view controller for display.

Vendor Requirements

- Specify APNS Cert and FCM sender ID per team.
